1. Introduction

Problem Statement

Investors often face challenges in making data-driven decisions when allocating investments between stocks and bonds. These decisions become more complex when considering factors such as risk tolerance, investment horizon, and market volatility. The **Investment Portfolio Decision Support System (DSS)** is designed to assist users in determining optimized stock and bond allocations based on user-specific inputs and risk profiles.

Motivation and Context

Investing involves balancing risk and reward while considering long-term objectives and uncertainties. Many investors struggle to:

1. Identify suitable investment alternatives.
2. Quantify risk tolerance and returns.
3. Incorporate evolving market conditions.

The DSS provides a structured solution by integrating utility models, Monte Carlo simulations, and portfolio optimization techniques.

Targeted Users

The primary users of this DSS include:

- Individual investors seeking optimized portfolios.
- Financial analysts providing investment recommendations.
- Retirees planning long-term savings.

2. Objectives and Needs

The DSS aims to provide:

1. **Personalized Portfolio Allocation:** Generate optimized investment allocations for stocks and bonds based on risk tolerance.
2. **Monte Carlo Simulations:** Model portfolio growth and uncertainties over time.
3. **Usability and Flexibility:** Allow users to input personalized parameters (e.g., age, horizon, risk tolerance).

Goals and Challenges

| Goal | Challenge |
|----------------------------------|--|
| Optimize portfolio allocation | Handling data for diverse stock/bond tickers |
| Model investment uncertainties | Simulating market fluctuations |
| Incorporate user preferences | Customizing utility models dynamically |
| Ensure usability and flexibility | Designing an intuitive user interface |

3. Alternatives and Attributes

Available Alternatives

The DSS incorporates alternatives for both **stocks** and **bonds**:

- **Stocks:** Top 50 stocks based on historical performance.
- **Bonds:** Top 20 bonds selected for risk-averse options.
- **ETFs:** Sector-specific ETFs for balanced investment.

Defined Attributes

| Attribute | Description |
|-------------|--|
| Mean Return | Average daily returns derived from historical data |
| Volatility | Standard deviation of daily returns |
| Horizon | Number of years to invest |

4. Development Process

Data Understanding

The `financial_data_last_year.csv` dataset includes:

- Historical stock and bond price data.
- Attributes like `mean_return`, `volatility`, and `utility_score` derived using Python.

| Example Data Columns |
|-------------------------|
| AAPL.3 (Closing Prices) |
| TSLA.3 |
| SPY.3 |

Model and Utility Function Development

The utility function incorporates three key components:

1. **Return Utility (u_r)**: Based on mean returns.
2. **Risk Utility (u_σ)**: Inverse of volatility.
3. **Horizon Utility (u_h)**: Weighted based on the time horizon.

Utility Function Formula:

$$U_{\text{Total}} = w_r * u_r + w_\sigma * u_\sigma + w_h * u_h$$

Where:

- w_r = Weight for returns
- w_σ = Weight for risk
- w_h = Weight for horizon

5. Utility Model and Weighting

Utility Function and Calculations

The **utility function** forms the backbone of the DSS as it quantifies the value of different investment alternatives based on the user's risk tolerance, expected return, and investment horizon. It assigns a weighted score to each investment option, allowing for optimal selection.

Utility Function Formula

The total utility U_{Total} for each investment is calculated as:

$$U_{Total} = w_r * u_r + w_\sigma * u_\sigma + w_h * u_h$$

Where:

- U_{Total} : The overall utility score.
- u_r : **Return utility** — Utility derived from the mean return of the investment.
- U_σ : **Risk utility** — Utility inversely proportional to the volatility (risk) of the investment.
- u_h : **Horizon utility** — Utility derived from the time horizon (number of years) for investment.
- W_r, w_σ, w_h : Weights assigned based on the user's **risk tolerance**.

Components of the Utility Function

1. Return Utility (u_r):

Return utility is proportional to the mean return of the investment. It rewards investments with higher expected returns.

$$U_r = \text{Mean Return}$$

2. Risk Utility (u_σ):

Risk utility penalizes investments with high volatility. It is modeled as the **inverse of volatility** to reflect risk aversion:

$$U_\sigma = 1 / \text{Volatility} \quad (\text{if Volatility} > 0)$$

If volatility equals zero (rare in practice), the risk utility is assigned a value of zero to avoid computational errors.

3. Horizon Utility (u_h):

Horizon utility reflects the benefit of long-term investments. It scales linearly with the investment horizon in years:

$$U_h = \text{Investment Horizon (years)}$$

Weight Assignment

Weights w_r, w_σ, w_h are dynamically adjusted based on the user's **risk tolerance**. This ensures the utility function aligns with the user's preferences.

| Risk Tolerance | Return Weight (w_r) | Risk Weight (w_σ) | Horizon Weight (w_h) |
|----------------|-------------------------|----------------------------|--------------------------|
| Low | 0.3 | 0.5 | 0.2 |
| Moderate | 0.4 | 0.3 | 0.3 |
| High | 0.5 | 0.2 | 0.3 |

Utility Function in Action

The DSS calculates the utility score for each investment using the formula:

$$U_{\text{Total}} = w_r * \text{Mean Return} + w_\sigma * (1 / \text{Volatility}) + w_h * \text{Horizon}$$

For example:

- **Stock A** has a mean return of 0.002, volatility of 0.01, and the investment horizon is 10 years.
- User selects a **Moderate Risk Profile**: $w_r = 0.4$, $w_\sigma = 0.3$, $w_h = 0.3$. The utility components are:

$$U_r = 0.002, u_\sigma = 1 / 0.01 = 100, u_h = 10$$

The total utility score is:

$$U_{\text{Total}} = (0.4 * 0.002) + (0.3 * 100) + (0.3 * 10) = 0.0008 + 30 + 3 = 33.0008$$

Each investment alternative is scored using this methodology, and the DSS ranks investments based on their utility scores.

6. Risk Analysis

Uncertainty in Investments

The DSS evaluates uncertainty through **Monte Carlo simulations**. Results highlight:

- Mean expected portfolio value.
- Range of outcomes (5th and 95th percentiles).

Simulation Results

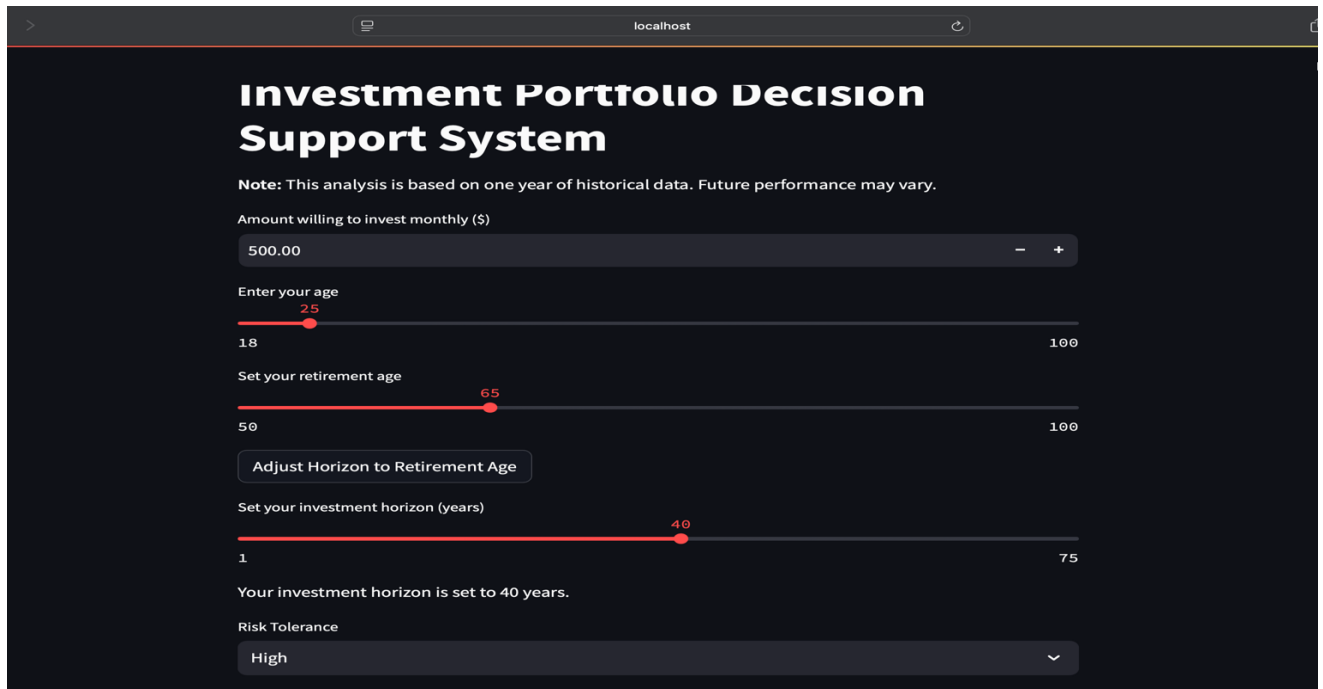

Example Output (40-year horizon):

- **Total Investment:** \$240,000
- **Mean Portfolio Value:** \$931,525
- **5th Percentile:** \$312,501
- **95th Percentile:** \$2,025,203

7. User Interface and Usability

Screenshots of DSS

1. **Input Parameters:**
 - User inputs monthly investments, age, retirement horizon, and risk tolerance.

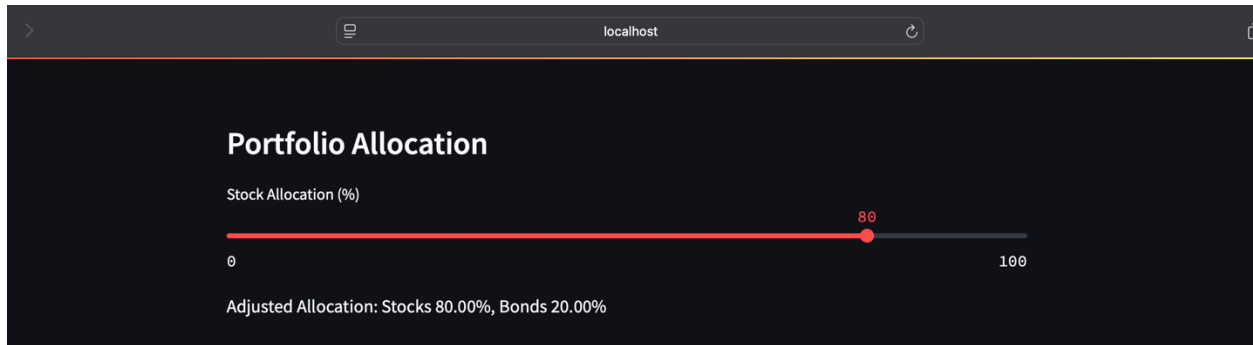

The screenshot displays the user interface of the Investment Portfolio Decision Support System (DSS) running on a web browser at localhost. The interface has a dark theme and includes the following elements:

- Title:** Investment Portfolio Decision Support System
- Note:** This analysis is based on one year of historical data. Future performance may vary.
- Amount willing to invest monthly (\$):** A numeric input field set to 500.00, with minus and plus buttons for adjustment.
- Enter your age:** A slider control ranging from 18 to 100, with a red dot indicating the selected age of 25.
- Set your retirement age:** A slider control ranging from 50 to 100, with a red dot indicating the selected age of 65.
- Adjust Horizon to Retirement Age:** A button that likely synchronizes the investment horizon with the retirement age.
- Set your investment horizon (years):** A slider control ranging from 1 to 75, with a red dot indicating the selected horizon of 40 years.
- Feedback:** A message stating "Your investment horizon is set to 40 years."
- Risk Tolerance:** A dropdown menu currently set to "High".

2. Portfolio Allocation:

- Adjust stock-bond allocations dynamically.

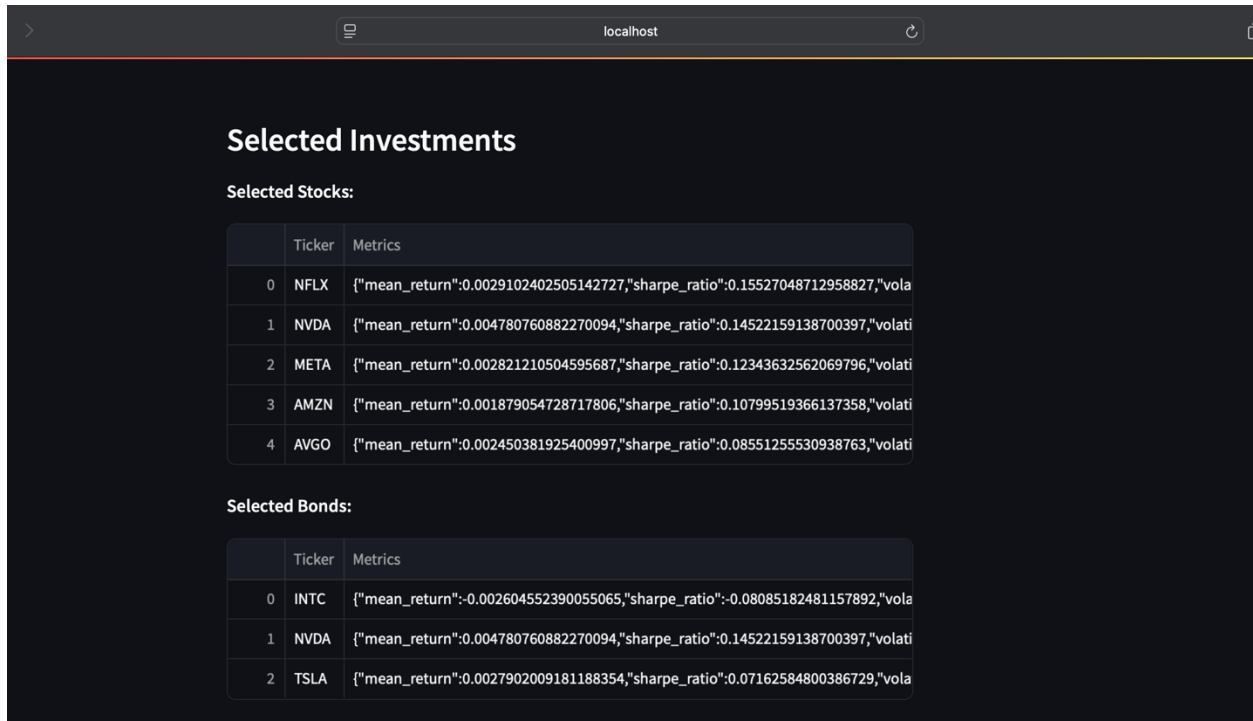

3. Utility Scores:

- Table displaying mean return, volatility, and utility scores.

| All Available Investments with Improved Utility Scores | | | | |
|--|-------------|------------|--------------|---------------|
| | mean_return | volatility | sharpe_ratio | utility_score |
| JNJ | -0.0001 | 0.0095 | -0.0113 | 33.0414 |
| DIS | 0.001 | 0.0164 | 0.0612 | 24.1711 |
| TXN | 0.0008 | 0.0175 | 0.0481 | 23.4283 |
| QCOM | 0.0008 | 0.0241 | 0.0351 | 20.3098 |
| MDT | 0.0003 | 0.0112 | 0.0224 | 29.885 |
| NFLX | 0.0029 | 0.0187 | 0.1553 | 22.6721 |
| HD | 0.0011 | 0.0127 | 0.0825 | 27.714 |
| XLRE | 0.0006 | 0.0103 | 0.0539 | 31.3773 |
| PG | 0.0007 | 0.0097 | 0.0733 | 32.608 |
| CVX | 0.0004 | 0.012 | 0.0339 | 28.6823 |
| | | | | |

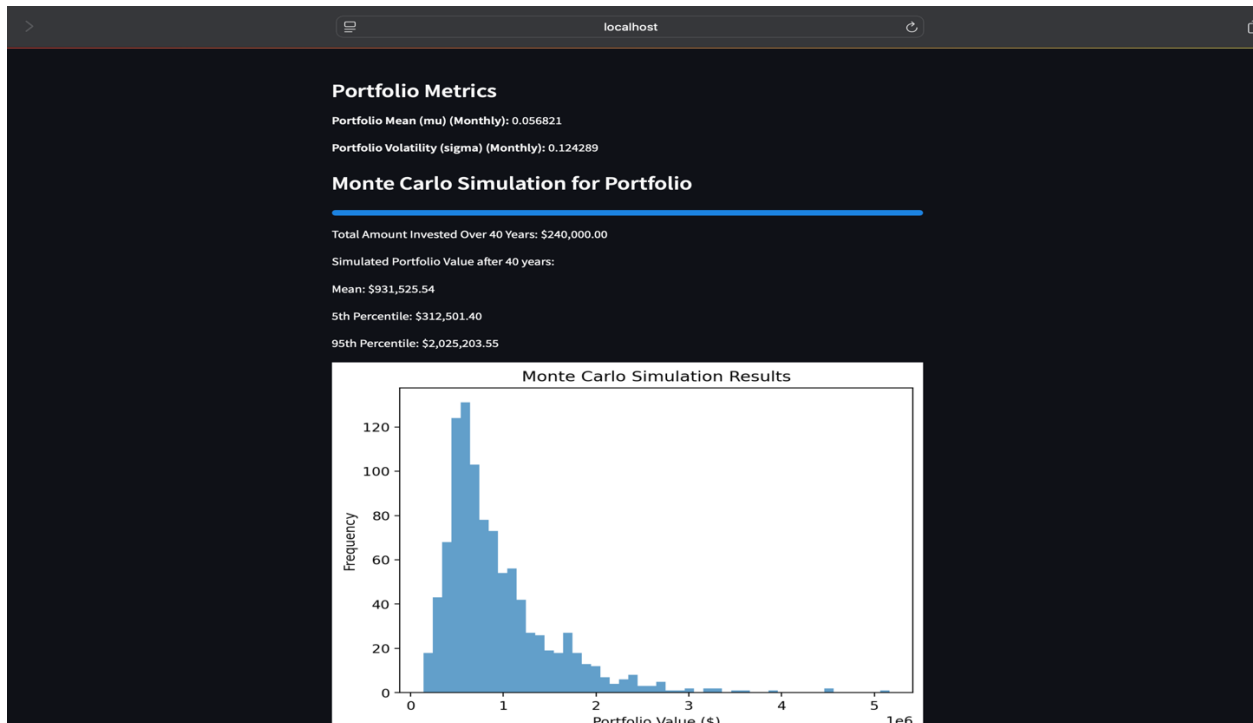

4. Optimized Investments:

- Selected stocks and bonds displayed with metrics.

5. Monte Carlo Visualization:

- Histogram showing portfolio growth under uncertainty.

8. Results and Interpretation

Portfolio Optimization Outcomes

The DSS recommends a portfolio based on:

1. User's **risk profile**.
2. Utility scores for selecting top-performing assets.

Portfolio Metrics

| Metric | Value |
|--------------------------|--------|
| Portfolio Mean (Monthly) | 0.0568 |
| Portfolio Volatility | 0.1242 |

Simulation Insights

- Monte Carlo simulation results indicate potential future portfolio values.
- The **5th and 95th percentiles** provide a range of possible outcomes.

9. Challenges and Limitations

Challenges Faced

1. **Yahoo Finance API Limitations:**
 - Limited data requests led to the use of a static dataset.
2. **Data Cleaning:**
 - Ensuring consistent and clean financial data for analysis.

Limitations

- Static dataset restricts real-time analysis.
- Simplified utility function may not capture all market behaviors.

10. Conclusion and Recommendations

The Investment Portfolio DSS effectively assists users in making data-driven investment decisions. By leveraging utility functions, portfolio optimization, and Monte Carlo simulations, the system:

- Provides personalized recommendations.
- Models investment uncertainties over time.

Future Enhancements:

1. Integrate live APIs for real-time data analysis.
2. Expand asset coverage beyond top 50 stocks and bonds.
3. Add advanced risk metrics for better decision-making.
